

II.1 Discrete signals

#### Representation

A discrete signal can represented:

- graphically
- ▶ in table form
- as a vector: x[n] = [..., 0, 0, 1, 3, 4, 5, 0, ...]
  - $\triangleright$  an **arrow** indicates the origin of time (n = 0).
  - ▶ if the arrow is missing, the origin of time is at the first element
  - the dots ... indicate that the value remains the same from that point onwards

Examples: at blackboard

Notation: x[4] represents the value of the fourth sample in the signal x[n]

### Basic signals

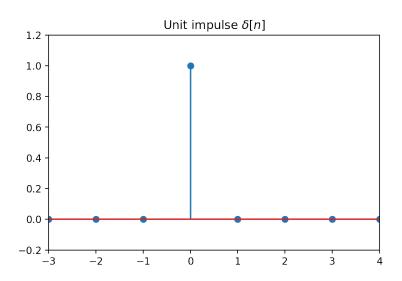

Some elementary signals are presented below.

#### Unit impulse

Contains a single non-zero value of 1 located at time 0. It is denoted with  $\delta[{\it n}].$ 

$$\delta[n] = \begin{cases} 1 & \text{if } n = 0 \\ 0 & \text{otherwise} \end{cases}.$$

## Representation

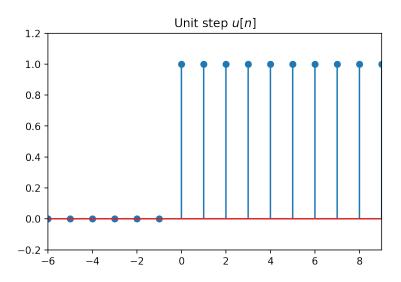

### Unit step

#### Unit step

It is denoted with u[n].

$$u[n] = \begin{cases} 1 & \text{if } n \ge 0 \\ 0 & \text{otherwise} \end{cases}.$$

## Representation

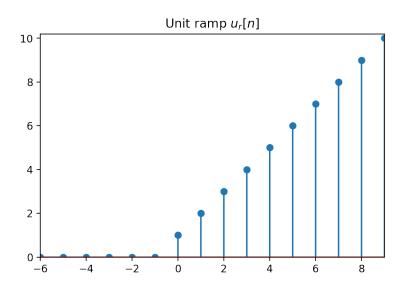

### Unit ramp

#### Unit ramp

It is denoted with  $u_r[n]$ .

$$u_r[n] = \begin{cases} n & \text{if } n \geq 0 \\ 0 & \text{otherwise} \end{cases}.$$

## Representation

## Exponential signal

#### Exponential signal

It does not have a special notation. It is defined by:

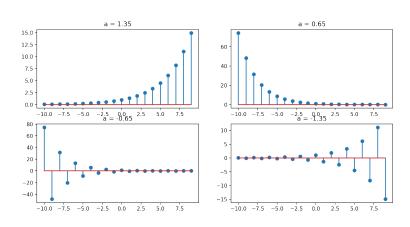

$$x[n] = a^n$$
.

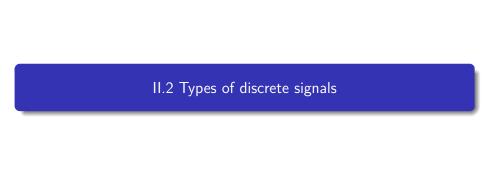

a can be a real or a complex number. Here we consider only the case when a is real.

Depending on the value of a, we have four possible cases:

- 1.  $a \ge 1$
- 2. 0 < a < 1
- 3. -1 < a < 0
- 4.  $a \le 1$

### Representation

### Signals with finite energy

▶ The energy of a discrete signal is defined as

$$E = \sum_{n=-\infty}^{\infty} (x[n])^2.$$

- ▶ If *E* is finite, the signal is said to have finite energy.
- Examples:
  - unit impulse has finite energy
  - unit step does not

#### Connection with DEDP class

Cross-link with DEDP course:

$$E = \|\mathbf{x} - \mathbf{0}\|^2 = \|\mathbf{x}\|^2$$

- ► Energy of a signal = squared Euclidean distance to 0
  - geometric interpretation: squared length of the segment from 0 to the point x
  - holds for continuous signals as well:

$$E = \|\mathbf{x}\|^2 = \int_{-\infty}^{\infty} x^2(t) dt$$

## Signals with finite power

The average power of a discrete signal is defined as

$$P = \lim_{N \to \infty} \frac{\sum_{n=-N}^{N} (x[n])^2}{2N+1}.$$

- ▶ In other words, the average power is the average energy per sample.
- ▶ If *P* is finite, the signal is said to have finite power.
- ➤ A signal with finite energy has finite power (P = 0 if the signal has infinite length). A signal with infinite energy can have finite or infinite power.
- **Example:** unit step has finite power  $P = \frac{1}{2}$  (proof at blackboard).

#### Connection with DEDP class

- ightharpoonup Average power = temporal average squared value  $X^2$ 
  - ▶ i.e. average value of the square of samples

## Periodic and non-periodic signals

► A signal is called **periodic** if its values repeat themselves after a certain time (known as **period**).

$$x[n] = x[n + N]), \forall t$$

- ▶ The **fundamental period** of a signal is the minimum value of *N*.
- Periodic signals have infinite energy, and finite power equal to the power of a single period.

### Even and odd signals

▶ A real signal is **even** if it satisfies the following symmetry:

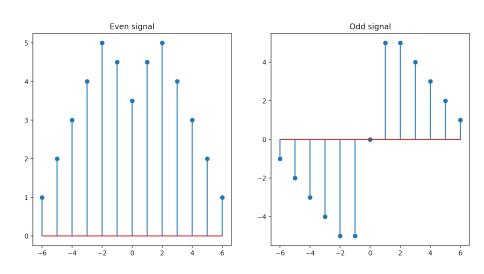

$$x[n] = x[-n], \forall n.$$

▶ A real signal is **odd** if it satisfies the following anti-symmetry:

$$-x[n] = x[-n], \forall n.$$

► There exist signals which are neither even nor odd.

## Even and odd signals: example

## Even and odd parts of a signal

Every signal can be written as the sum of an even signal and an odd signal:

$$x[n] = x_e[n] + x_o[n]$$

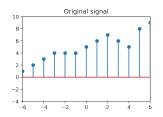

▶ The even and the odd parts of the signal can be found as follows:

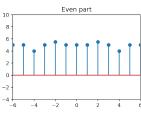

$$x_e[n] = \frac{x[n] + x[-n]}{2}.$$

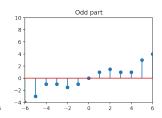

$$x_o[n] = \frac{x[n] - x[-n]}{2}.$$

▶ Proof: check that  $x_e[n]$  is even,  $x_o[n]$  is odd, and their sum is x[n]

### Even and odd parts: example

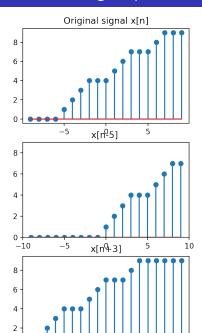

### Time shifting

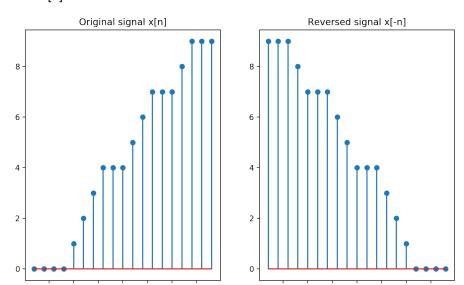

- ▶ The signal x[n-k] is x[n] delayed with k time units
  - ▶ Graphically, x[n-k] is shifted k units to the **right** compared to the original
- ▶ The signal x[n+k] is x[n] anticipated with k time units
  - ▶ Graphically, x[n+k] is shifted k units to the **left** compared to the original signal.

### Time shifting: representation

#### Time reversal

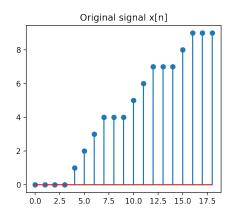

▶ Changing the variable n to -n produces a signal x[-n] which mirrors x[n].

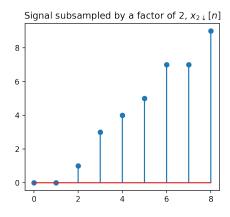

## Subsampling

- ► **Subsampling** by a factor of M = keep only 1 sample from every M of the original signal
  - ► Total number of samples is reduced M times

$$x_{M\downarrow}[n] = x[Mn]$$

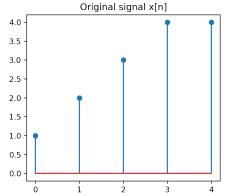

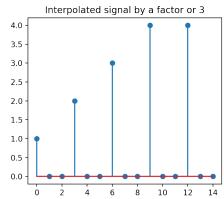

### Interpolation

- Interpolation by a factor of L adds (L-1) zeros between two samples in the original signal
  - ► Total number of samples increases L times

$$x_{L\uparrow} = \begin{cases} x\left[\frac{n}{L}\right] & \text{if } \frac{n}{L} \in \mathbb{N} \\ 0 & \text{otherwise} \end{cases}.$$

## Mathematical operations

A signal x[n] can be **scaled** by a constant A, i.e. each sample is multipled by A:

$$y[n] = Ax[n].$$

► Two signals  $x_1[n]$  and  $x_2[n]$  can be **summed** by summing the individual samples:

$$y[n] = x_1[n] + x_2[n]$$

Two signals  $x_1[n]$  and  $x_2[n]$  can be **multiplied** by multipling the individual samples:

$$y[n] = x_1[n] \cdot x_2[n]$$

II.4 Discrete systems

#### **Definition**

- ➤ System = a device or algorithm which produces an output signal based on an input signal
- ▶ We will only consider systems with a single input and a single output
- Figure here: blackboard.
- Common notation:
  - x[n] is the input
  - ▶ y[n] is the output
  - ► H is the system.

#### **Notations**

Notations:

$$y[n] = H[x[n]]$$

("the system H applied to the input x[n] produces the output y[n]")

$$x[n] \stackrel{H}{\rightarrow} y[n]$$

("the input x[n] is transformed by the system H into y[n]")

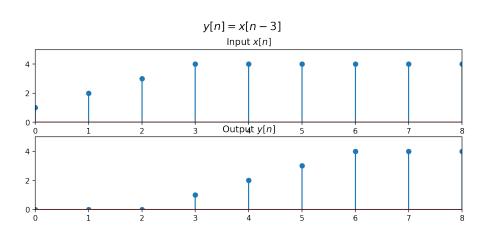

### Equations

Usually, a system is described by the input-output equation (or difference equation) which expains how y[n] is defined in terms of x[n].

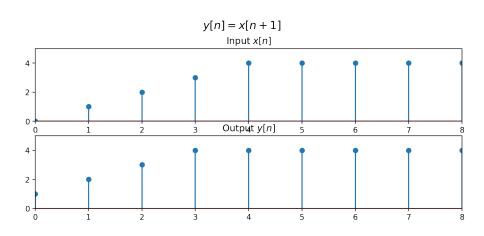

#### Examples:

- 1. y[n] = x[n] (the identity system)
- 2. y[n] = x[n-3]
- 3. y[n] = x[n+1]
- 4.  $y[n] = \frac{1}{3}(x[n+1] + x[n] + x[n-1])$
- 5.  $y[n] = \max(x[n+1], x[n], x[n-1])$
- 6.  $y[n] = (x[n])^2 + \log_{10} x[n-1]$
- 7.  $y[n] = \sum_{k=-\infty}^{n} x[k] = x[n] + x[n-1] + x[n-2] + ...$

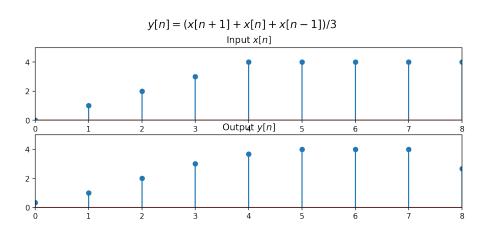

# Example

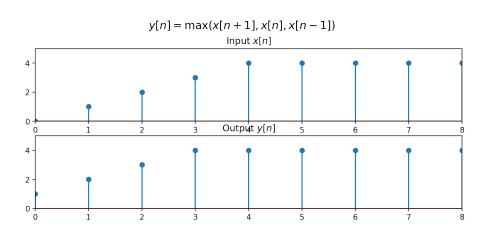

# Example

## Example

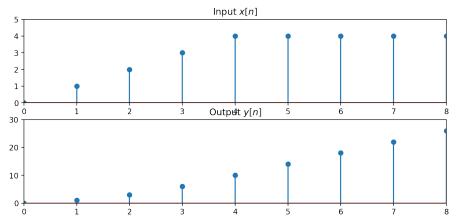

## Example

## Example

$$y[n] = \sum_{k=-\infty}^{n} x[k] = x[n] + x[n-1] + x[n-2] + \dots$$

#### Recursive systems

Some systems can/must be written in recursive form

$$y[n] = y[n-1] + x[n],$$

- Must always specify initial conditions
  - i.e. initial value (e.g. y[-1] = 2.5)
  - ▶ if not mentioned, assume they are 0 ("relaxed system")
  - they represent the internal state of the system at the starting moment
- For recursive systems, the output signal depends on both the input signal and on the initial conditions
  - different initial conditions lead to different outputs, even if input signal is the same
  - ▶ a recursive system with non-zero initial conditions can produce an output signal even in the absence of an input (x[n] = 0)

#### Representation of systems

- ► The operation of a system can be described graphically (see examples on blackboard):
  - summation of two signals
  - scaling of a signal with a constant
  - multiplication of two signals
  - delay element
  - anticipation element
  - other blocks for more complicated math operations

# Memoryless / systems with memory

- ► Memoryless (or static): output at time *n* depends only on the input from the same moment *n*
- Otherwise, the system has memory (dynamic)
- Examples:
  - ightharpoonup memoryless:  $y[n] = (x[n])^3 + 5$
  - with memory:  $y[n] = (x[n])^3 + x[n-1]$

## Memoryless / systems with memory

- ► Memory of size *N*:
  - output at time n y[n] depends only up to the last N inputs, x[n-N], x[n-(N-1)], ...x[n],
  - if N is finite: the system has **finite memory**
  - ightharpoonup if  $N=\infty$ , the system has **infinite memory**
- Examples:
  - finite memory of order 4: y[n] = x[n] + x[n-2] + x[n-4]
  - infinite memory: y[n] = 0.5y[n-1] + 0.8x[n]
    - recursive systems usually have infinite memory

## Memoryless / systems with memory

- ► An input sample has an effect on the output only for the next *N* time moments
- ► For systems infinite memory, any sample influences **all** the following samples, forever
  - but, if system is stable, the influence gets smaller and smaller

## Time-Invariant and Time-Variant systems

► A relaxed system *H* is **time-invariant** if and only if:

$$x[n] \stackrel{H}{\rightarrow} y[n]$$

implies,  $\forall x[n], \forall k$ , that

$$x[n-k] \stackrel{H}{\to} y[n-k]$$

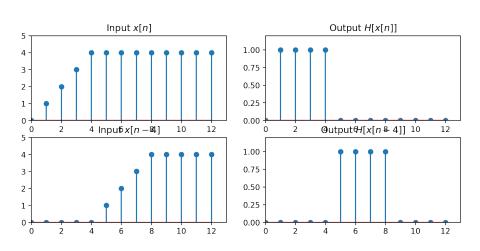

- ▶ Delaying the input signal with k will only delay the output with the same amount, otherwise the output is not affected
  - Must be true for all input signals, for all possible delays (positive or negative)
- Otherwise, the system is said to be time-variant

## Time-Invariant and Time-Variant systems

- Examples:
  - y[n] = x[n] x[n-1] is time-invariant
  - $y[n] = n \cdot x[n]$  is not time-invariant
- A system is time-invariant if it depends on n only through the input signal x[n]

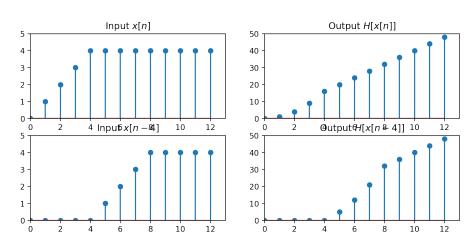

### Example

#### Time-invariant system y[n] = x[n] - x[n-1]

## Another example

Time-variant system  $y[n] = n \cdot x[n]$ 

#### Linear and nonlinear systems

► A system *H* is **linear** if:

$$H[ax_1[n] + bx_2[n]] = aH[x_1[n]] + bH[x_2[n]].$$

- Composed of two parts:
  - Applying the system to a sum of two signals = applying the system to each signal, and adding the results
  - Scaling the input signal with a constant a is the same as scaling the output signal with a
- ▶ The same relation will be true for a sum of many signals, not just two

#### Linear and nonlinear systems

- Advantage of linear systems
  - Complicated input signals can be decomposed into a sum of smaller parts
  - ► The system can be applied to each part independently
  - Then the results are added back
- Examples:
  - linear system: y[n] = 3x[n] + 5x[n-2]
  - ▶ nonlinear system:  $y[n] = 3(x[n])^2 + 5x[n-2]$

#### Linear and nonlinear systems

- For a system to be linear, the input samples x[n] must not undergo non-linear transformations.
- ► The only transformations of the input x[n] allowed to take place in a linear system are:
  - scaling (multiplication) with a constant
  - delaying
  - summing different delayed versions of the signal (not summing with a constant)

#### Causal and non-causal systems

- ▶ Causal: the output y[n] depends only on the current input x[n] and the past values x[n-1], x[n-2]..., but not on the future samples x[n+1], x[n+2]...
- ▶ Otherwise the system is **non-causal**.
- A causal system can operate in real-time
  - we need only the input samples from the past
  - non-causal systems need samples from the future
- Examples:
  - y[n] = x[n] x[n-1] is causal
  - ▶ y[n] = x[n+1] x[n-1] is non-causal
  - ightharpoonup y[n] = x[-n] is non-causal

## Stable and unstable systems

▶ **Bounded** signal: if there exists a value *M* such that all the samples of the signal or smaller than M, in absolute values

$$x[n] \in [-M, M]$$

$$|x[n]| \leq M$$

- ► **Stable** system: if for any bounded input signal it produces a bounded output signal
  - not necessarily with the same M
  - known as BIBO (Bounded Input -> Bounded Output)
- In other words: when the input signal has bounded values, the output signal does not go towards  $\infty$  or  $-\infty$ .

## Stable and unstable systems

- Examples:
  - $y[n] = (x[n])^3 x[n+4]$  is stable
  - $y[n] = \frac{1}{x[n]-x[n-1]}$  is unstable
  - $y[n] = \sum_{k=-\infty}^{n} x[k] = x[n] + x[n-1] + x[n-2] + \dots$  is unstable

## Linear Time-Invariant (LTI) systems

- ▶ Notation: An LTI system (Linear Time-Invariant) is a system which is simultaneously linear and time-invariant.
- LTI systems can be described via either (or both):
  - 1. the impulse response h[n]
  - 2. the difference equation

$$y[n] = -\sum_{k=1}^{N} a_k y[n-k] + -\sum_{k=1}^{M} b_k x[n-k]$$
  
= -a\_1 y[n-1] - a\_2 y[n-2] - ... - a\_N y[n-N] + b\_0 x[n] + b\_1 x[n-1]

### The impulse response

▶ **Impulse response** of a system = output (response) of when the input signal is the impulse  $\delta[n]$ :

$$h[n] = H(\delta[n])$$

- ► The impulse response of a LTI system fully characterizes the system:
  - based on h[n] we can compute the response of the system to **any** input signal
  - all the properties of LTI systems can be described via characteristics of the impulse response

## Signals are a sum of impulses

- Any signal can be composed as **a sum of scaled and delayed** impulses  $\delta[n]$ .
- Example:  $x[n] = \{3, 1, -5, 0, 2\} = 3\delta[n] + \delta[n-1] 5\delta[n-2] + 2\delta[n-2]$
- ► In general

$$x[n] = \sum_{k=-\infty}^{\infty} x[k]\delta[n-k]$$

i.e. a sum of impulses  $\delta[n]$ , delayed with k and scaled with the corresponding value x[k]

#### Convolution

- ▶ The response of a LTI system to a sum of impulses, delayed with k and scaled with x[k], is a sum of impulse responses, delayed with k and scaled with x[k].
  - The input signal is composed of separate impulses
  - ► LTI system -> each impulse will generate its own response
  - output signal is the sum of impulse responses, delayed and scaled

$$y[n] = H(x[n])$$

$$= H\left(\sum_{k=-\infty}^{\infty} x[k]\delta[n-k]\right)$$

$$= \sum_{k=-\infty}^{\infty} x[k]H(\delta[n-k])$$

$$= \sum_{k=-\infty}^{\infty} x[k]h[n-k].$$

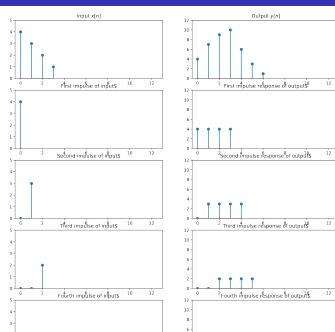

#### Convolution

▶ This operation = the **convolution** of two signals x[n] and h[n]

$$x[n] * h[n] = \sum_{k=-\infty}^{\infty} x[k]h[n-k]$$

The response of a LTI system to an input signal x[n] is the convolution of x[n] with the system's impulse response h[n]

## Example

The convolution equation can be interpreted in two ways:

- 1. The output signal y[n] = a sum of a lot of impulse responses h[n], each one delayed by k (hence [n-k]) and scaled by x[k]
  - one for each sample in the input signal
  - explain at blackboard

$$x[n] * h[n] = \sum_{k=-\infty}^{\infty} x[k] h[n-k]$$

2. Each output sample y[n] = a weighted sum of the input samples around it

$$y[n] = \dots + h[2] \cdot x[n-2] + h[1] \cdot x[n-1] + h[0] \cdot x[n] + h[n+1] \cdot x[n+1] + \dots$$

- ▶ If h[n] has finite length (e.g. non-zero only between h[-2]...h[2]), then there are only a few terms in the sum
  - Example at blackboard

$$x[n] * h[n] = \sum_{k=-\infty}^{\infty} h[k] \mathbf{x}[\mathbf{n} - k]$$

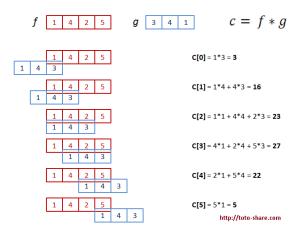

Figure 1: Convolution as weighted sum

image from http://www.stokastik.in

► Watch the following:

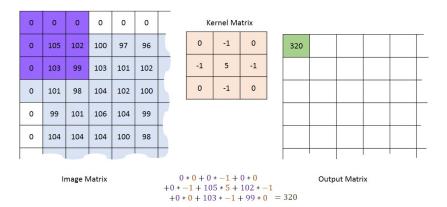

https://www.youtube.com/watch?v=ulKbLD6BRJA

#### 2D convolution

- ► Convolution can be applied in 2D (for images)
- ▶ The input signal = an image I[x, y]
- ▶ The impulse response (the *kernel*) = a matrix H[x, y]
- ► The convolution result:

$$Y[x,y] = I * H = \sum_{i=-\infty}^{\infty} \sum_{j=-\infty}^{\infty} I[x-i,y-j] \cdot H[i,j]$$

#### 2D convolution

# Convolution with horizontal and vertical strides = 1

Figure 2: 2D Convolution as weighted sum

▶ image from http://machinelearninguru.com

#### 2D Convolution

► Watch this:

http://machinelearninguru.com/computer\_vision/basics/convolution/convolution\_layer.html

#### 2D Convolution

- ► Simple image effects with 2D convolutions:
  - ▶ the "kernel" = the impulse response H[x, y]

see https://en.wikipedia.org/wiki/Kernel\_(image\_processing)

▶ What are their 1D counterparts?

### Properties of convolution

Convolution is commutative (the order of the two signals doesn't matter):

$$x[n] * h[n] = \sum_{k=-\infty}^{\infty} x[k]h[n-k] = h[n] * x[n] = \sum_{k=-\infty}^{\infty} h[k]x[n-k]$$

- . Proof: make variable change  $(n-k) \rightarrow l$ , change all in equation
  - Convolution is associative

$$(a[n] * b[n]) * c[n] = a[n] * (b[n] * c[n])$$

. (No proof)

### Properties of convolution

▶ The unit impulse is neutral element for convolution

$$a[n] * \delta[n] = \delta[n] * a[n] = a[n]$$

- . Proof: equation
  - ► Convolution is a linear operation

$$(\alpha \cdot a[n] + \beta \cdot b[n]) * c[n] = \alpha(\cdot a[n] * c[n]) + \beta \cdot (b[n] * c[n])$$

Proof: by linearity of the corresponding system

# Properties of LTI systems expressed with h[n]

#### 1. Identity system

- A system with  $h[n] = \delta[n]$  produces an response equal to the input,  $y[n] = x[n], \forall x[n].$
- ▶ Proof:  $\delta[n]$  is neutral element for convolution.

#### 2. Series connection is commutative

- ▶ LTI systems connected in series can be interchanged in any order
- ▶ Proof: by commutativity of convolution.
- ▶ LTI systems connected in series are equivalent to a single system with

$$h_{equiv}[n] = h_1[n] * h_2[n] * ... * h_N[n]$$

#### 3. Parallel connection means sum

LTI systems connected in parallel are equivalent to a single system with

$$h_{equiv}[n] = h_1[n] + h_2[n] + ... + h_N[n]$$

#### 4. Response of LTI systems to unit step

▶ If the input signal is u[n], the response of the system is

$$s[n] = u[n] * h[n] = h[n] * u[n] = \sum_{k=-\infty}^{\infty} h[k]u[n-k] = \sum_{k=-\infty}^{n} h[k]$$

.

- Proof:
  - ▶ The signal  $\sum_{k=-\infty}^{n} h[k]$  is a discrete-time integration of h[n]
  - ▶ The unit step u[n] iteslf is the discrete-time integral of the unit impulse:

$$u[n] = \sum_{k=-\infty}^{n} \delta[k]$$
$$\delta[n] = u[n] - u[n-1]$$

- ► Therefore the system response to the integral of the impulse = the integral of the system response to the impulse
- ► The interchanging of the integration with the system is due to the linearity of the system and is valid for all signals:

$$H\left(\sum_{k=-\infty}^{n} x[k]\right) = \sum_{k=-\infty}^{n} H(x[k])$$

## 1. Causal LTI systems and their h[n]

If a LTI system is causal, then

$$h[n] = 0, \forall n < 0$$

Proof:

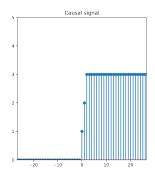

- $y[n] = \sum_{k=-\infty}^{\infty} x[k]h[n-k],$
- y[n] does not depend on x[n+1], x[n+2], ...
- it means that these terms are multiplied with 0
- the value x[n+1] is multiplied with h[n-(n+1)] = h[-1], x[n+2] is multiplied with h[n-(n+2)] = h[-2], and so on
- Therefore:

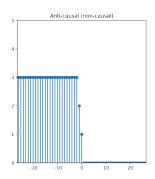

$$h[n] = 0, \forall n < 0$$

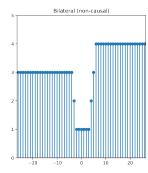

## Causal signals and causal systems

- A signal which is 0 for n < 0 is called a *causal signal*
- ▶ Otherwise the signal is *non-causal*
- We can say that a system is causal if and only if it has a causal impulse response
- Further definitions:
  - ▶ a signal which 0 for n > 0 is called an *anti-causal* signal
  - ▶ a signal which has non-zero values both for some n > 0 and for some n < 0 (and thus is neither causal nor non-causal) is called *bilateral*.

# Example

## 2. Stable systems and their h[n]

► Considering a bounded input signal,  $|x[n]| \le A$ , the absolute value of the output is:

$$|y[n]| = |\sum_{k=-\infty}^{\infty} x[k]h[n-k]|$$

$$\leq \sum_{k=-\infty}^{\infty} |x[k]h[n-k]|$$

$$= \sum_{k=-\infty}^{\infty} |x[k]||h[n-k]|$$

$$\leq A \sum_{k=-\infty}^{\infty} |h[n-k]|$$

► Therefore a LTI system is stable if

$$\sum_{k=-\infty}^{\infty} |h[n]| < \infty$$

.

3. Memoryless systems and their h[n] (Exercise)

#### **Exercises:**

- ▶ What can we say about the impulse response h[n] of a memoryless system?
- ▶ What about a system with finite memory *M*?

## Support

- ► The **support** of a discrete signal = the smallest interval of *n* such that the signal is 0 everywhere outside the interval.
- Examples: at whiteboard
- Depending on the support of the impulse response, discrete LTI systems can be FIR or IIR systems.

#### FIR systems

- ► A Finite Impulse Response (FIR) system has an impulse response with finite support
  - i.e. the impulse response is 0 outside a certain interval.
- For a causal system:
  - ▶ h[n] = 0 for n < 0
  - ▶ therefore h[n] = 0 for n < 0 or  $n \ge M$ , for some M
  - The convolution becomes:

$$y[n] = \sum_{k=0}^{M} h[k]x[n-k] = h[0] \cdot x[n] + h[1] \cdot x[n-1] + \dots h[M] \cdot x[n-M]$$

► For a causal FIR system, the output is a linear combination of the last *M* input samples (has finite memory *M*)

#### IIR systems

- ► An Infinite Impulse Response (FIR) system has an impulse response with infinite support
  - ▶ i.e. the impulse response never becomes completely 0 forever.
- ▶ Causal system: the output y[n] potentially depends on all the preceding input samples
  - from the convolution equation
- ► An IIR system has infinite memory

## Recursive / non-recursive implementations

- **Recursive** implementation: compute y[n] based partly on the previous output samples y[n-1], y[n-2], ....
  - more efficient
- For a recursive LTI system, the output y[n] depends on:
  - ▶ the last N samples of the output, y[n-1], ... y[n-N]
  - ▶ and the current and the last M samples of the input, x[0], x[1], ... x[n-M].
- Example:

$$y[n] = \frac{1}{n+1} \sum_{0}^{n} x[n]$$

can be rewritten in recursive form:

$$y[n] = n \cdot y[n-1] + x[n]$$

## Recursive / non-recursive implementations

- **Non-recursive** system: the output y[n] is computed based only on last M samples of the input,  $x[0], x[1], \ldots x[n-M]$ .
- ► FIR systems can always be implemented non-recursively, but may also be implemented in a recursive way
- IIR systems can only be implemented recursively
  - otherwise they would need infinite memory

#### Initial conditions for recursive systems

- Recursive systems rely on previous outputs -> the previous values must be always available
- We need some starting values at the start moment (the initial conditions of the system)
- Notes:
  - Output signal depends on the input and on the initial conditions
  - A system with non-zero initial conditions produces an output even when the input signal is zero
  - ▶ This output is called zero-input response,  $y_{zi}[n]$
  - ► A system with initial conditions equal to 0 is called *relaxed*
  - The output of a relaxed system to an input signal is called *zero-state* response,  $y_{zs}[n]$  (also called *forced response*)
- ► For linear systems, the output of a system is always the sum of the forced response and the natural response:

$$y[n] = y_{zs}[n] + y_{zi}[n]$$
