Digital Signal Processing

Chapter V. Digital filtering

Response of LTI systems to harmonic signals

- ▶ We consider an LTI system with h[n]
- ▶ Input signal = complex harmonic (exponential) signal $x[n] = Ae^{j\omega_0 n}$
- ► Output signal = convolution

$$y[n] = \sum_{k=-\infty}^{\infty} h[k]x[n-k]$$
$$= \sum_{k=-\infty}^{\infty} h[k]e^{-j\omega_0 k}Ae^{j\omega_0 n}$$
$$= H(\omega_0) \cdot x[n]$$

▶ $H(\omega_0)$ = Fourier transform of h[[n]] evaluated for $\omega = \omega_0$

Eigen-function

- Complex exponential signals are eigen-functions (funcții proprii) of LTI systems:
 - ▶ output signal = input signal × a (complex) constant
- $ightharpoonup H(\omega_0)$ is a constant that multiplies the input signal
 - Amplitude of input gets multiplies by $|H(\omega_0)|$
 - ▶ Phase of input signal is added with $\angle H(\omega_0)$
- ► Why are sin/cos/exp functions important?
 - ▶ If input signal = sum of complex exponential (= coses + sinuses),
 - since the system is linear,
 - then output = same sum of complex exponentials, each scaled with some coefficients

Response to cosine and sine

► Cosine / sine = sum of two exponentials, via Euler

$$\cos(\omega t) = \frac{e^{j\omega t} + e^{-j\omega t}}{2}$$

 $\sin(\omega t) = \cos(\omega t - \frac{\pi}{2})$

- ► System is linear and real =>
 - ightharpoonup amplitude is multiplied by $|H(\omega_0)|$
 - ▶ phase increases by $\angle H(\omega_0)$
- See proof at blackboard

Frequency response

- ► Naming:
 - \blacktriangleright $H(\omega) =$ **frequency response** of the system
 - $|H(\omega)|$ = amplitude response (or magnitude response)
 - $ightharpoonup \angle H(\omega) =$ phase response
- ▶ Magnitude response is non-negative: $|H(\omega)| \ge 0$
- ▶ Phase response is an angle: $\angle H(\omega) \in (-\pi, pi]$
 - Phase response may have jumps of 2π (wrapped phase)
 - ▶ Stitching the pieces in a continuous function = phase *unwrapping*
 - Unwrapped phase: continuous function, may go outside interval $(-\pi, pi]$
 - (-π, pr] ► Example: at black
 - Example: at blackboard

Permanent and transient response

- ▶ The above harmonic signals start at $n = -\infty$, not at 0.
- ▶ What if the signal starts at some time n = 0?
- ► Total response = transient response + permanent response
 - ▶ transient response goes towards 0 as $n \to \infty$
 - permanent response = the above
- ► So the above relations are valid only in **permanent regime**
 - ▶ i.e. after the transient regime has passed
 - i.e. after the transient response has practically vanished
 - \blacktriangleright i.e. when the signal started very long ago (from $n=-\infty$)
- Example at blackboard

Permanent response of LTI systems to periodic inputs

- ightharpoonup Assume the input x[n] is periodic with period N
- ▶ Then it can be represented as a Fourier series:

$$x[n] = \sum_{k=0}^{N-1} c_k e^{j2\pi kn/N}$$

ightharpoonup Since the system is linear, the output to each component k is

$$c_k H\left(\frac{2\pi}{N}k\right) e^{j2\pi kn/N}$$

So the total output is:

$$y[n] = \sum_{k=0}^{N-1} c_k H\left(\frac{2\pi}{N}k\right) e^{j2\pi kn/N}$$

▶ The output is still periodic, same period, same frequencies

Response of LTI systems to non-periodic signals

▶ The output = input convolution with impulse response

$$y[n] = x[n] * h[n]$$

$$Y(\omega) = X(\omega) \cdot H(\omega)$$

- In polar form:
 - modulus get multiplied
 - phases get added
- ► The system **attenuates/amplifies** the input frequencies and **changes their phases**
- \blacktriangleright $H(\omega) =$ the transfer function
- ightharpoonup H(z) =the system function
- \blacktriangleright $H(\omega) = H(z = e^{j\omega})$ if unit circle is in CR

Power spectral density

- ▶ The poles and zeros of $S(\omega)$ come in pairs (z, 1/z and p, 1/p)

Digital filters

- ► LTI systems are also known as **filters** because their transfer function shapes (*filters*) the frequencies of the input signals
- ▶ The transfer function can be found from H(z) and $z = e^{j\omega}$
- ► Alternatively, the transfer function can be found by the **geometrical method** based on the locations of poles and zeros

Ideal filters

- ▶ Ideal low-pass filter: example at whiteboard
- ▶ Ideal band-pass filter: example at whiteboard
- ▶ Ideal high- pass filter: example at whiteboard
- ▶ Ideal band-stop filter: example at whiteboard
- ▶ Ideal all-pass filter (*changes the phase*): idem

Linear-phase filters

Consider a constant filter with linear phase function:

$$H(\omega) = C \cdot e^{-j\omega n_0}$$

► The output signal is

$$Y(\omega) = X(\omega) \cdot C \cdot e^{-j\omega n_0}$$

$$y[n] = C \cdot x[n - n_0]$$

- ▶ Linear phase means **just** a **delaying** of the input signal
 - Fourier property: $x[n-n_0] < --> X(\omega)e^{-j\omega n_0}$

Group delay

- \blacktriangleright = The time delay experienced by a component of frequency ω when passing through the filter
- ► **Group delay** of the filter:

$$au_{\mathsf{g}}(\omega) = rac{d\Theta(\omega)}{d\omega}$$

► Linear phase = constant group delay = all frequencies delayed the same = whole signal delayed

Filter distortions

- ▶ When a filter is non-ideal:
 - non-constant amplitude -> amplitude distortions
 - non-linear phase -> phase distortions
- ▶ Phase distortions may be tolerated by certain applications
 - e.g. human ears are insensitive to phase distortions of sounds

Filter order

- ▶ The **order** of a filter = maximum degree in numerator or denominator of H(z)
 - ▶ i.e. largest power of z
- Any filter can be implemented, in general, with this number of unit delay blocks (z^{-1})
- ► Higher order -> better filter transfer function
 - closer to ideal filter
 - more complex to implement
 - more delays (bad)
- Lower order
 - worse transfer function (not close to ideal)
 - simpler, cheaper
 - faster response

Filter design by pole and zero placements

- Based on geometric method
- ▶ The gain coefficient must be found by separate condition
 - i.e. specify the desired magnitude response at one frequency
- ► Examples at blackboard

Linear-phase FIR filters

What type of filters can have linear phase?

- ► IIR filters cannot have linear phase (no proof)
- Only FIR filters can have linear phase, and only if they satisfy some symmetry conditions

Symmetry conditions for linear-phase FIR

- Let filter have an impulse response of length M (order is M-1)
- ▶ The filter coefficients are $h[0], \ldots h[M-1]$
- ► Linear-phase is guaranteed in two cases
- Positive symmetry

$$h[n] = h[M - 1 - n]$$

Negative symmetry (anti-symmetry)

$$h[n] = -h[M-1-n]$$

Cases of linear-phase FIR

- Proofs at blackboard
- 1. Positive symmetry, M = odd
- 2. Positive symmetry, M = even
- 3. Negative symmetry, M = odd
- 4. Negative symmetry, M = even
- ▶ Check constraints for H(0) and $H(\pi)$
- ▶ For what types of filters is each case appropriate?

Particular classes of filters

- Digital resonators
 - very selective band pass filters
 - poles very close to unit circle
 - ▶ may have zeros in 0 or at 1/-1
- Notch filters
 - have zeros exactly on unit circle
 - will completely reject certain frequencies
 - has additional poles to make the rejection band very narrow
- Comb filters
 - = periodic notch filters

Digital oscillators

- Oscillator = a system which produces an output signal even in absence of input
- ► Has a pair of complex conjugate poles **exactly on unit circle**
- ► Example at blackboard

Inverse filters

- ► Sometimes is necessary to **undo** a filtering
 - e.g. undo attenuation of a signal passed through a channel
- ▶ Inverse filter: has inverse system function:

$$H_I(z) = \frac{1}{H(z)}$$

- ▶ Problem: if H(z) has zeros outside unit circle, $H_I(z)$ has poles outside unit circle -> unstable
- Examples at blackboard
